## 1. INTRODUCTION

Let  $X$  be a partially ordered set with order  $\leq$ , let  $\mathcal{V} = \mathcal{V}(X)$  be the linear space of bounded real functions on  $X$  and  $\mathcal{M} = \mathcal{M}(X) \subset \mathcal{V}$  the convex cone of isotone functions in  $\mathcal{V}$ , i.e., functions  $h$  satisfying  $h(x) \leq h(y)$  whenever  $x, y \in X$ ,  $x \leq y$ . Given a weighted uniform norm  $\|\cdot\|_w$  on  $\mathcal{V}$  defined by

$$\|f\|_w = \sup w(x) |f(x)|, \quad f \in \mathcal{V}, \quad (1.1)$$

where  $w$  in  $\mathcal{V}$  is a weight function satisfying  $w(x) \geq \delta > 0$  for all  $x \in X$ , the problem is to find  $g$  in  $\mathcal{M}$ , if one exists, such that

$$\|f - g\|_w = \inf_{h \in \mathcal{M}} \|f - h\|_w. \quad (1.2)$$

We call this problem the problem of isotone optimization with respect to the weighted uniform norm (1.1). Instead of (1.1) we may consider other norms, e.g., the  $l_p$  norm,  $1 \leq p < \infty$ . Let  $X = \{x_1, x_2, \dots, x_n\}$  be a finite partially ordered set. For each  $p$ ,  $1 \leq p < \infty$ , define an  $l_p$  norm  $\|\cdot\|_w^p$  by

$$\|f\|_w^p = \left( \sum_{i=1}^n w_{p,i} |f_i|^p \right)^{1/p}, \quad (1.3)$$

where  $f = \{f_i\}_{i=1}^n$  is a function on  $X$  and  $w_p = \{w_{p,i}\}_{i=1}^n > 0$  is a given weight function. Since  $X$  is finite, we identify any function  $f$  with the sequence  $\{f_1, f_2, \dots, f_n\}$  where  $f_i = f(x_i)$  and for convenience write  $f = \{f_i\}_{i=1}^n$ . The class  $\mathcal{M}$ , of isotone functions in this case is the set of all  $h = \{h_i\}_{i=1}^n$  on  $X$  satisfying

$$h_i \leq h_j \text{ whenever } x_i, x_j \in X \text{ and } x_i \leq x_j. \quad (1.4)$$

\* Part I appears in this Journal **12**, 146–159 (1974). Both parts are based on a section of the author's dissertation submitted in partial fulfillment of the requirement for the degree of Ph.D. at the University of California, Berkeley in 1971. This research was supported by the National Science Foundation and the Office of Naval Research. The material was revised under Grant GK-32712 from the National Science Foundation.

The problem of isotone optimization with respect to the  $l_p$  norm is: given  $\{f_i\}_{i=1}^n$  find  $g_p = \{g_{p,i}\}_{i=1}^n$  in  $\mathcal{M}$ , if one exists, such that

$$\|f - g_p\|_w^p = \inf_{h \in \mathcal{M}} \|f - h\|_w^p. \quad (1.5)$$

In [11] we considered the problem (1.2) and characterized the set of all its solutions. In this article we investigate the problem (1.2) further and show its relationship to the problem (1.5). In Section 2 we show that when  $X$  is finite, under certain conditions on the weight functions  $w_p$ , the solution of (1.5) converges as  $p \rightarrow \infty$  to a solution of problem (1.2) for some  $w = \{w_i\}_{i=1}^n$ . In Section 3 we point out a norm reducing property of a particular solution of (1.2) when  $w(x) = 1$  for all  $x \in X$ . Specifically if  $f_i \in \mathcal{V}$ ,  $i = 1, 2$  and  $f_i^0$ ,  $i = 1, 2$  be the corresponding particular solutions of (1.2), we show that  $\|f_1^0 - f_2^0\|_w \leq \|f_1 - f_2\|_w$  holds. In Section 4 we investigate the differentiability properties of the solutions of (1.2) when  $X = [a, b]$ , a closed interval of the real line and in Section 5 we construct algorithms to compute these solutions and establish relevant rates of convergence.

The problem (1.5) arises in certain aspects of statistical analysis involving the restricted maximum likelihood estimation. To give a simple example, maximizing the joint density of  $n$  independent normal distributions  $N(\mu_i, \sigma_i^2)$ ,  $i = 1, 2, \dots, n$  with an ordering restriction on the means  $\mu_i$  is the same as solving an isotone optimization problem with respect to the  $l_2$  norm. See [2, 10]. Owing to the applications to statistics this problem and a more general version which involves minimization of a function defined on  $\mathcal{V}$  and satisfying certain conditions, are extensively investigated. For a history of the problem see [2]. See also [3], [7], and [12]. The solution  $g_p = \{g_{p,i}\}_{i=1}^n$  of the problem (1.5) for  $1 < p < \infty$ , is known to be given by (See [12]).

$$\begin{aligned} g_{p,i} &= \max_{\{U: i \in U\}} \min_{\{L: i \in L\}} u_p(L \cap U) \\ &= \min_{\{L: i \in L\}} \max_{\{U: i \in U\}} u_p(L \cap U), \quad \text{for all } i, \end{aligned} \quad (1.6)$$

where  $L$  and  $U$  are lower and upper sets respectively and unique  $u_p(L \cap U)$  satisfies

$$\sum_{i \in L \cap U} w_{p,i} |f_i - u_p(L \cap U)|^p \leq \sum_{i \in L \cap U} w_{p,i} |f_i - u|^p \quad (1.7)$$

for all real  $u$ . (We call  $L \subset X$  a lower set if  $x_i \in L$  and  $x_j \in X$ ,  $x_j \leq x_i$  implies that  $x_j \in L$ . Similarly  $U \subset X$  is an upper set if  $x_i \in U$  and  $x_j \in X$ ,  $x_j \geq x_i$  implies that  $x_j \in U$ .) When  $p = 2$  it is easy to see that (1.7) gives

$$u_2(L \cap U) = \left( \sum_{i \in L \cap U} w_{2,i} f_i \right) / \left( \sum_{i \in L \cap U} w_{2,i} \right)$$

and from (1.6) it may be seen that  $g_2$  has an elegant expression. We shall use these expressions in Section 2.

## 2. CONVERGENCE PROPERTIES OF THE ISOTONE OPTIMIZATION PROBLEM WITH RESPECT TO THE $l_p$ NORM

Let  $X = \{x_1, x_2, \dots, x_n\}$  be finite partially ordered. In this case the norm (1.1) takes the form

$$\|f\|_w = \max_{1 \leq i \leq n} w_i |f_i|, \quad (2.1)$$

where  $f = \{f_i\}_{i=1}^n$ ,  $w = \{w_i\}_{i=1}^n > 0$  and  $\mathcal{M}$  consists of all  $h$  satisfying (1.4). For convenience denote the problem (1.2) for this case by  $P_\infty$  and the problem (1.5) by  $P_p$ ,  $1 \leq p < \infty$ . We investigate the convergence of the solution  $g_p$  of the problem  $P_p$  as  $p \rightarrow \infty$ .

**THEOREM 1.** *Assume that there exists  $w = \{w_i\}_{i=1}^n > 0$  such that*

$$0 < \liminf_{p \rightarrow \infty} (w_{p,i}/w_i^p) \leq \limsup_{p \rightarrow \infty} (w_{p,i}/w_i^p) < \infty \quad (2.2)$$

*for all  $i$ . Then the solution  $g_p = \{g_{p,i}\}_{i=1}^n$  of the problem  $P_p$  converges as  $p \rightarrow \infty$  to a solution  $g_\infty = \{g_{\infty,i}\}_{i=1}^n$  of the problem  $P_\infty$  with weights  $w = \{w_i\}_{i=1}^n$ . Specifically*

$$\begin{aligned} g_{\infty,i} &= \lim_{p \rightarrow \infty} g_{p,i} = \max_{\{U: i \in U\}} \min_{\{L: i \in L\}} u_\infty(L \cap U) \\ &= \min_{\{L: i \in L\}} \max_{\{U: i \in U\}} u_\infty(L \cap U), \end{aligned} \quad (2.3)$$

*for all  $i$ , where  $L$  and  $U$  are lower and upper subsets of  $X$  respectively and  $u_\infty(L \cap U)$  is the unique real number satisfying*

$$\max_{i \in L \cap U} w_i |f_i - u_\infty(L \cap U)| \leq \max_{i \in L \cap U} w_i |f_i - u| \quad \text{for all } u. \quad (2.4)$$

*Remarks.* (i) If there exist  $\delta, m > 0$  such that  $0 < \delta \leq w_{p,i} \leq m$  for all  $p$  and  $i$ , then (2.2) holds if and only if  $w_i = 1$  for all  $i$ . In such a case the  $P_\infty$  problem has unit weights.

(ii) The solution of the problem  $P_p$ ,  $1 < p < \infty$  is unique and is given by (1.6). When  $f = \{f_i\}_{i=1}^n$  is not isotone, the  $P_\infty$  problem has an infinite number of distinct solutions. This follows from the results in [11]. Theorem 1 indicates that exactly one of the solutions of the  $P_\infty$  problem is a limit of the solutions of the  $P_p$  problem when the hypothesis of Theorem 1 holds.

(iii) Compare (2.3) with the results in Ref. [11] of part I of this article.

*Proof of Theorem 1.* We first introduce some notation and prove two lemmas. For a fixed  $f = \{f_i\}_{i=1}^n$  we define functions  $\tau_p: R^n \rightarrow R$  and  $\kappa_p: R \rightarrow R$  for  $1 \leq p \leq \infty$  by

$$\tau_p(\mathbf{u}) = \sum_{i=1}^n w_{p,i} |f_i - u_i|^p, \quad 1 \leq p < \infty,$$

$$\tau_\infty(\mathbf{u}) = \max_{1 \leq i \leq n} w_i |f_i - u_i|,$$

$$\kappa_p(u) = \sum_{i=1}^n w_{p,i} |f_i - u|^p, \quad 1 \leq p < \infty,$$

$$\kappa_\infty(u) = \max_{1 \leq i \leq n} w_i |f_i - u|,$$

where  $\mathbf{u} = (u_1, u_2, \dots, u_n) \in R^n$  and  $u \in R$ .

LEMMA 1. Assume (2.2) holds, then

$$\lim_{p \rightarrow \infty} (\tau_p(\mathbf{u}))^{1/p} = \tau_\infty(\mathbf{u}), \quad (2.5)$$

and

$$\lim_{p \rightarrow \infty} (\kappa_p(u))^{1/p} = \kappa_\infty(u), \quad (2.6)$$

the convergence being uniform on compact sets in the domain of the respective function.

*Proof.* From (2.2) it follows that there exist real numbers  $\delta_1, \delta_2 > 0$  and  $p_0 \geq 1$  such that  $\delta_1 \leq w_{p,i}/w_i^p \leq \delta_2$  for all  $i$  for all  $p \geq p_0$ . Hence

$$\tau_p(\mathbf{u}) = \sum_{i=1}^n (w_{p,i}/w_i^p)(w_i |f_i - u_i|^p) \leq (n\delta_2)(\tau_\infty(\mathbf{u}))^p,$$

for all  $p \geq p_0$ . Also by finiteness of  $X$ , there exists  $i_0$  depending upon  $\mathbf{u}$  such that  $w_{i_0} |f_{i_0} - u_{i_0}| = \tau_\infty(\mathbf{u})$ . Hence

$$\tau_p(\mathbf{u}) \geq w_{p,i_0} |f_{i_0} - u_{i_0}|^p = (w_{p,i_0}/w_{i_0}^p)(w_{i_0} |f_{i_0} - u_{i_0}|)^p \geq \delta_1(\tau_\infty(\mathbf{u}))^p.$$

It follows that

$$|\tau_p(\mathbf{u})^{1/p} - \tau_\infty(\mathbf{u})| \leq \max\{|(n\delta_2)^{1/p} - 1|, |\delta_1^{1/p} - 1|\} \tau_\infty(\mathbf{u}).$$

Since  $\tau_\infty(\mathbf{u})$  is continuous in  $\mathbf{u}$ , it is bounded on a compact domain. Hence the uniform convergence of  $\tau_p(\mathbf{u})^{1/p}$  to  $\tau_\infty(\mathbf{u})$  follows. Thus (2.5) is established. (2.6) follows from (2.5) with  $\mathbf{u} = (u, u, \dots, u)$ .

Lemma 1 corresponds to the well-known result in measure theory concerning the function spaces  $L_p(X, \Sigma, \mu)$ ,  $1 \leq p \leq \infty$  that when  $\mu(X) < \infty$ , the  $L_p$  norm converges pointwise to the  $L_\infty$  norm as  $p \rightarrow \infty$ . See, e.g., [1]. Our setting owing to the introduction of the weight function  $w_p$ , which may vary with  $p$ , differs somewhat from the setting of the  $L_p$  spaces. Hence a condition such as (2.2) is required to prove convergence.

LEMMA 2. Suppose for each  $p$ ,  $1 < p < \infty$  the real number  $u_p$  satisfies  $\kappa_p(u_p) \leq \kappa_p(u)$  for all  $u$ . Then  $u_p$  is unique, limit  $u_p = u_\infty$  exists as  $p \rightarrow \infty$  and  $\kappa_\infty(u_\infty) \leq \kappa_\infty(u)$  for all  $u$ . Further,  $\kappa_\infty$  has a unique minimizer.

*Proof.* Note that  $\kappa_p(u) \rightarrow \infty$  as  $|u| \rightarrow \infty$  for  $1 \leq p \leq \infty$ . Since  $\kappa_p$  is continuous in  $u$ , by using compactness arguments we may show that a minimizer of  $\kappa_p$  exists for  $1 \leq p \leq \infty$ . It is easy to see that  $\kappa_p(u)$  for  $1 < p < \infty$  is strictly convex in  $u$  (see [5]). Hence, the minimizer  $u_p$  is unique. If  $v_\infty$  satisfies  $\kappa_\infty(v_\infty) \leq \kappa_\infty(u)$  for all  $u$ , then using the finiteness of  $X$  we have  $\kappa_\infty(v_\infty) = w_{i_1}(x_{i_1} - v_\infty) = w_{i_2}(v_\infty - x_{i_2})$  for some  $i_1, i_2$ ,  $1 \leq i_1, i_2 \leq n$ . It follows that the minimizer  $v_\infty$  of  $\kappa_\infty$  is also unique.

It is easy to see that

$$\min_{1 \leq i \leq n} x_i \leq u_p \leq \max_{1 \leq i \leq n} x_i,$$

for all  $p$ ,  $1 < p < \infty$ . Now let  $t_k = u_{p_k}$ ,  $k = 1, 2, \dots$  be any subsequence of  $u_p$  such that  $p_k \rightarrow \infty$  as  $k \rightarrow \infty$ . Since  $t_k$  are bounded there exists a convergent subsequence, say  $t_{k_j} \rightarrow t_\infty$ . We then have, letting  $r_j = p_{k_j}$  for convenience,

$$(\kappa_{r_j}(t_{k_j}))^{1/r_j} \leq (\kappa_{r_j}(u))^{1/r_j} \quad \text{for all } u.$$

Since  $\kappa_p^{1/p}$  is continuous and converges to  $\kappa_\infty$  uniformly on compact sets (Lemma 1), on letting  $j \rightarrow \infty$  we have  $\kappa_\infty(t_\infty) \leq \kappa_\infty(u)$  for all  $u$ . It follows that  $t_\infty = v_\infty$ , since the minimizer is unique. Thus any subsequence  $u_{p_k}$  of  $u_p$  such that  $p_k \rightarrow \infty$  as  $k \rightarrow \infty$  contains in turn a subsequence converging to  $v_\infty$ . Hence, limit  $u_p = v_\infty$  as  $p \rightarrow \infty$  and the assertions made in the lemma hold with  $u_\infty = v_\infty$ .

Now we proceed to the proof of Theorem 1. The solution  $g_p = \{g_{p,i}\}_{i=1}^n$  of the problem  $P_p$ ,  $1 < p < \infty$  is given by (1.6). Considering  $L \cap U$  instead of  $X$  in Lemma 2 we conclude that

$$\lim_{p \rightarrow \infty} u_p(L \cap U) = u_\infty(L \cap U)$$

exists and (2.4) holds. Since the number of lower and upper sets is finite, from (1.6) it follows that the limit of  $g_{p,i}$  exists as  $p \rightarrow \infty$  for all  $i$  and (2.3) holds for some  $g_{\infty,i}$ . It now suffices to show that  $\{g_{\infty,i}\}_{i=1}^n$  is a solution of

the problem  $P_\infty$ . Since  $\{g_{p,i}\}_{i=1}^n$  is isotone for each  $p$ ,  $\{g_{\infty,i}\}_{i=1}^n$  also has this property. Clearly

$$\min_{1 \leq i \leq n} x_i \leq g_{p,i} \leq \max_{1 \leq i \leq n} x_i \quad \text{for all } p, \quad \text{all } i.$$

Using the definition of  $\{g_{p,i}\}_{i=1}^n$  we have  $\tau_p(\mathbf{g}_p)^{1/p} \leq \tau_p(\mathbf{u})^{1/p}$  for all  $\mathbf{u} \in R^n$ . Letting  $p \rightarrow \infty$  we conclude from (2.5) that  $\tau_\infty(\mathbf{g}_\infty) \leq \tau_\infty(\mathbf{u})$  for all  $\mathbf{u} \in R^n$ . Hence  $\{g_{\infty,i}\}_{i=1}^n$  is a solution of the problem  $P_\infty$ . The proof of Theorem 1 is now complete.

### 3. NORM REDUCING PROPERTY OF A SOLUTION OF THE ISOTONE OPTIMIZATION PROBLEM WITH RESPECT TO THE UNIFORM NORM

Let  $X$  be an arbitrary partially ordered set and  $w(x) = 1$  for all  $x \in X$ . Then the norm (1.1) becomes the uniform norm  $\|\cdot\|$ , where

$$\|f\| = \sup_{x \in X} |f(x)|, \quad f \in \mathcal{V}. \quad (3.1)$$

We consider the problem (1.2) with  $\|\cdot\|_w$  replaced by  $\|\cdot\|$ . For  $f \in \mathcal{V}$  define  $f^0 \in \mathcal{V}$  by

$$f^0 = (1/2) \left( \sup_{\{z: z \leq x\}} f(z) + \inf_{\{z: x \leq z\}} f(z) \right), \quad x \in X. \quad (3.2)$$

It is easy to see that  $f^0$  is isotone.

**THEOREM 2.** *Let  $f, f_1, f_2 \in \mathcal{V}$ . Then*

$$(i) \quad \|f - f^0\| = \min_{h \in \mathcal{M}} \|f - h\|, \quad (3.3)$$

*i.e.,  $f^0$  solves the problem (1.2) for the norm  $\|\cdot\|$ .*

$$(ii) \quad \|f_1^0 - f_2^0\| \leq \|f_1 - f_2\|, \quad (3.4)$$

*i.e., the norm reducing property holds.*

*Proof.*

(i) Let

$$\theta = (1/2) \sup_{\{(x,y) \in X \times X: x \leq y\}} (f(x) - f(y)), \quad (3.5)$$

$$g(x) = \sup_{\{z: z \leq x\}} f(z) - \theta, \quad x \in X, \quad (3.6)$$

$$\bar{g}(x) = \inf_{\{z: x \leq z\}} f(z) + \theta, \quad x \in X, \quad (3.7)$$

then

$$f^0 = (1/2)(g + \bar{g}). \quad (3.8)$$

We know from the results of Section 2 of [11] that

$$\theta = \min_{h \in \mathcal{M}} \|f - h\| = \|f - g\| = \|f - \bar{g}\|. \quad (3.9)$$

But since  $g \leq f^0 \leq \bar{g}$ , (i) again follows from the results in Section 2 of [11].

(ii) Let  $\theta_i, g_i, \bar{g}_i, i = 1, 2$  be defined by (3.5), (3.6), (3.7), respectively, with  $f_i, i = 1, 2$ , in the right-hand sides of these expressions. Again (3.8), (3.9) hold with  $\theta, f, f^0, g$  and  $\bar{g}$  replaced respectively by  $\theta_i, f_i, f_i^0, g_i$  and  $\bar{g}_i$  for each  $i = 1, 2$ . Let  $x \in X$  and  $\epsilon > 0$ . Then by the definition of  $g_i, \bar{g}_i$  there exist  $z_1, z_2 \in X$  such that  $z_1 \leq x \leq z_2$  and

$$\begin{aligned} g_1(x) &\leq f_1(z_1) - \theta_1 + \epsilon, \\ \bar{g}_2(x) &\geq f_2(z_2) + \theta_2 - \epsilon. \end{aligned}$$

Also

$$\begin{aligned} \bar{g}_1(x) &\leq f_1(z_2) + \theta_1, \\ g_2(x) &\geq f_2(z_1) - \theta_2. \end{aligned}$$

Using (3.8) we may derive from the above four inequalities the following:

$$f_1^0(x) - f_2^0(x) \leq (1/2)(f_1(z_1) - f_2(z_1)) + (1/2)(f_1(z_2) - f_2(z_2)) + \epsilon.$$

Hence

$$f_1^0(x) - f_2^0(x) \leq \|f_1 - f_2\| + \epsilon.$$

Interchanging subscripts 1 and 2 and noting that  $\epsilon, x$  are arbitrary we conclude that (3.4) holds. The proof is now complete.

*Remarks.* According to the results of Section 2 of [11] any  $g$  in  $\mathcal{M}$  satisfying  $g \leq g \leq \bar{g}$  minimizes  $\|f - h\|$  for  $h$  in  $\mathcal{M}$ . We have indeed isolated an  $f^0$  in  $\mathcal{M}$  from this infinite set of minimizers such that (3.4) holds. It is shown in the Ref. [8] of part I of this article that a similar result is true under certain conditions for the function space  $L_\infty(X, \Sigma, \mu)$ , where  $X$  is a totally ordered set. The result also holds for the  $L_2$  norm case. See Dykstra [4].

#### 4. DIFFERENTIABILITY PROPERTIES OF $g$ AND $\bar{g}$

We now consider the problem (1.2) with  $X = [a, b]$ , a closed interval of the real line. We showed in [11] that both  $g$  and  $\bar{g}$  solve the problem (1.2). Here

$$g(x) = \sup_{z \in [a, x]} (f(z) - \theta/w(z)), \quad x \in [a, b], \quad (4.1)$$

$$\bar{g}(x) = \inf_{z \in [x, b]} (f(z) + \theta/w(z)), \quad x \in [a, b], \quad (4.2)$$

and

$$\theta = \sup_{(x,y) \in S} \frac{w(x)w(y)}{w(x) + w(y)} (f(x) - f(y)),$$

where

$$S = \{(x, y) \in [a, b] \times [a, b]: x, y \in [a, b], x \leq y\}.$$

In this section we investigate the differentiability and other properties of  $g$  and  $\bar{g}$ .

We first introduce concepts called the Level and Descent Sets. Let  $f \in \mathcal{V}$  and define for each  $x \in [a, b]$  the following sets:

$$L(f, x) = \bigcup \{[x, y]: x < y \leq b \text{ and } f(z) = f(x) \text{ for all } z \in [x, y]\},$$

$$D_1(f, x) = \bigcup \{(x, y): x < y \leq b \text{ and } f(z) < f(x) \text{ for all } z \in (x, y)\},$$

$$D_2(f, x) = \bigcup \{[x, y]: x < y \leq b \text{ and } f(z) \leq f(x) \text{ for all } z \in [x, y]\}.$$

Define the Level Set  $L(f)$  and the Strong Descent Set  $D_1(f)$  by

$$L(f) = \bigcup_{x \in [a, b]} L(f, x),$$

$$D_1(f) = \bigcup_{x \in [a, b]} D_1(f, x).$$

Also define the Weak Descent Set  $D_2(f)$  by

$$D_2(f) = \bigcup_{x \in [a, b]} D_2(f, x).$$

We now state

LEMMA 3. *Let  $f \in \mathcal{C}$ .*

(i) *If  $L(f) \neq \emptyset$  then*

$$L(f) = \bigcup_{n=1}^{\infty} [\alpha_n, \beta_n], \quad a \leq \alpha_n < \beta_n \leq b \quad \text{for all } n,$$

where  $[\alpha_n, \beta_n]$  are disjoint closed intervals such that  $f(z) = f(\alpha_n)$  for all  $z \in [\alpha_n, \beta_n]$ .

(ii) *If  $D_1(f) \neq \emptyset$  then*

$$D_1(f) = \bigcup_{n=1}^{\infty} (\rho_n, \sigma_n), \quad a \leq \rho_n < \sigma_n \leq b \quad \text{for all } n,$$

where  $(\rho_n, \sigma_n)$  are disjoint open intervals such that  $f(z) < f(\rho_n)$  for all  $z \in (\rho_n, \sigma_n)$  and  $f(x) \leq f(\rho_n)$  for all  $x \in [a, \rho_n]$ .

(iii) If  $D_2(f) \neq \emptyset$  then

$$D_2(f) = \bigcup_{n=1}^{\infty} [\lambda_n, \mu_n], \quad a \leq \lambda_n < \mu_n \leq b \quad \text{for all } n,$$

where  $[\lambda_n, \mu_n]$  are disjoint closed intervals such that  $f(z) \leq f(\lambda_n)$  for all  $z \in [\lambda_n, \mu_n]$  and  $f(x) < f(\lambda_n)$  for all  $x \in [a, \lambda_n)$ .

Clearly, whenever  $L(f) \neq \emptyset$ ,  $D_2(f) \neq \emptyset$  we have,

$$L^{(0)}(f) = \text{interior of } L(f) = \bigcup_{n=1}^{\infty} (\alpha_n, \beta_n),$$

$$D_2^{(0)}(f) = \text{interior of } D_2(f) = \bigcup_{n=1}^{\infty} (\lambda_n, \mu_n).$$

We denote by  $f^{(k)}(x)$ , the  $k$ th derivative of  $f$  at  $x$ , if it exists. We define  $P$  as in Section 2 of [11] and recall that if  $f$  and  $w$  are continuous then so is  $g$ .

**THEOREM 3.** Let  $\mu^*$  be the Lebesgue measure on  $[a, b]$ .

(A) Let  $f, w \in \mathcal{C}$  then

- (i)  $(f \in \mathcal{M}) \Leftrightarrow (D_1(f) = \emptyset) \Leftrightarrow (D_2(f) = L(f))$
- (ii)  $L(g) = D_2(f - \theta/w) \supset P$
- (iii)  $\{x \in [a, b]: g(x) = f(x) - \theta/w(x)\} = [a, b] - D_1(f - \theta/w)$
- (iv)  $\{x \in [a, b]: g^{(n)}(x) = 0, n = 1, 2, \dots\} \supset D_2^{(0)}(f - \theta/w)$
- (v)  $g^{(1)}(x)$  may not exist at most on a set

$$E \subset [a, b] - D_2^{(0)}(f - \theta/w)$$

with  $\mu^*(E) = 0$ .

(B)  $\mu^*(D_2(f)) = \mu^*(D_2^{(0)}(f))$  for all  $f \in \mathcal{C}$ .

If  $f, w \in \mathcal{C}$ ,  $g \not\equiv \text{constant}$  and

$$\mu^*(D_2(f - \theta/w)) = \mu^*(D_2^{(0)}(f - \theta/w)) = b - a,$$

which, of course, implies from A(iv) that  $g^{(n)}(x) = 0$ ,  $\mu^*$ -a.e. on  $[a, b]$  for  $n = 1, 2, \dots$ , then both  $f$  and  $w$  cannot be absolutely continuous.

*Remarks.*

(i) A similar theorem may be stated for  $\bar{g}$ , but in this case we need

to modify the definitions of  $L$ ,  $D_1$  and  $D_2$  sets. For example, we may define the set  $D_1'$  as follows

$$D_1'(f, x) = \bigcup \{(y, x): a \leq y < x \quad \text{and} \quad f(z) > f(x) \\ \text{for all } z \in (y, x)\}, \quad x \in [a, b]$$

$$D_1'(f) = \bigcup_{x \in [a, b]} D_1'(f, x).$$

Similar modifications necessary for the definitions of other sets are evident.

(ii) We give below one example of special interest to illustrate the results of Theorem 3. It will be seen that  $g^{(1)}(x)$  does not exist on the set  $E = [a, b] - D_2^{(0)}(f - \theta/w)$  with  $\mu^*(E) = 0$ . (See Theorem 3, A(v).) Let  $[a, b] = [0, 1]$  and  $f: [0, 1] \rightarrow [0, 1]$  be the well-known Cantor ternary function, ([6], p. 138). Then  $f$  is nondecreasing continuous with range  $[0, 1]$ . Hence  $\theta = 0$  and  $g = \bar{g} = f$ . Let  $K$  be the Cantor ternary set. Then  $[0, 1] - K$  is the union of disjoint open intervals and  $f$  is constant on each of these intervals. Clearly  $D_2^{(0)}(f - \theta/w) = D_2^{(0)}(f) = [0, 1] - K$  and on  $[0, 1] - K$ ,  $f^{(1)}(x)$  exists and equals 0.  $f^{(1)}$  does not exist on  $E = K$ . It is a known fact that  $\mu^*(E) = 0$ .

We prove Lemma 3 before proceeding to the proof of Theorem 3.

*Proof of Lemma 3.* We prove (iii). The proofs for (i) and (ii) are similar. Let  $t \in D_2(f)$ . Define

$$\lambda_t = \inf\{x: t \in [x, y], a \leq x < y \leq b \text{ and } f(z) \leq f(x) \text{ for all } z \in [x, y]\},$$

$$\mu_t = \sup\{y: t \in [x, y], a \leq x < y \leq b \text{ and } f(z) \leq f(x) \text{ for all } z \in [x, y]\}.$$

There exist  $[x_n, y_n]$ ,  $n = 1, 2, \dots$  such that  $t \in [x_n, y_n]$ ,  $a \leq x_n < y_n \leq b$ ,  $f(z) \leq f(x_n)$  for all  $z \in [x_n, y_n]$  and  $x_n \rightarrow \lambda_t$  as  $n \rightarrow \infty$ . We may take  $x_{n+1} \leq x_n \leq x_1 < y_1$ . Since  $x_n \leq x_1 \leq t \leq y_1$  we have  $f(z) \leq f(x_1)$  for all  $z \in [x_1, y_1]$  and  $f(z) \leq f(x_n)$  for all  $z \in [x_n, t]$ . Hence  $f(z) \leq f(x_n)$  for all  $z \in [x_n, y_1]$ . Since  $f(x_{n+1}) \geq f(x_n)$ , using continuity of  $f$  we have  $f(\lambda_t) \geq f(z)$  for all  $z \in [\lambda_t, y_1]$ . Thus,  $\lambda_t \in D_2(f)$ . Suppose  $t \in [x, y]$ , where  $a \leq x < y \leq b$  and  $f(z) \leq f(x)$  for all  $z \in [x, y]$ , then  $x \in [\lambda_t, y]$  and  $f(\lambda_t) \geq f(z)$  for all  $z \in [\lambda_t, y]$ . Hence

$$\mu_t = \sup\{y: \lambda_t < y \leq b \text{ and } f(z) \leq f(\lambda_t) \text{ for all } z \in [\lambda_t, y]\}.$$

Clearly,  $\lambda_t < \mu_t$  and  $f(z) \leq f(\lambda_t)$  for all  $z \in [\lambda_t, \mu_t]$ . Thus  $[\lambda_t, \mu_t] \subset D_2(f)$ . Hence,

$$D_2(f) = \bigcup_{t \in D_2(f)} [\lambda_t, \mu_t].$$

Suppose  $u \in [\lambda_t, \mu_t]$  then  $\lambda_u \leq \lambda_t$  and  $\mu_u \geq \mu_t$ . Since  $t \in [\lambda_t, \mu_t]$  implies  $t \in [\lambda_u, \mu_u]$  we have  $\lambda_t \leq \lambda_u$  and  $\mu_t \geq \mu_u$ . Thus,  $[\lambda_t, \mu_t] = [\lambda_u, \mu_u]$ . The intervals are therefore disjoint and the countability follows since each of the intervals includes a distinct rational number.

Suppose now there exists  $x, a \leq x < \lambda_n$  for some  $n$  such that  $f(x) \geq f(\lambda_n)$ . Define

$$v = \inf\{u \in [x, \lambda_n] : f(u) = \max_{z \in [x, \lambda_n]} f(z)\}.$$

Then  $a \leq v < \lambda_n$  and  $f(z) \leq f(v)$  for all  $z \in [v, \lambda_n]$  which is a contradiction to the definition of  $\lambda_n$ .

LEMMA 4.

(i)  $(f \in \mathcal{M}) \Rightarrow (D_1(f) = \emptyset) \Leftarrow (D_2(f) = L(f))$ .

(ii) Suppose  $f \in \mathcal{C}$  then

$$(f \in \mathcal{M}) \Leftrightarrow (D_1(f) = \emptyset) \Leftrightarrow (D_2(f) = L(f)).$$

Proof of the lemma is simple. Note that if  $f \in \mathcal{V} - \mathcal{C}$  then  $D_1(f) = \emptyset$  does not imply that  $f \in \mathcal{M}$  or  $D_2(f) = L(f)$ . As an example take  $f: [0, 1] \rightarrow R$  defined by  $f(x) = 1, x \in [0, 1)$  and  $f(1) = 0$ . Similarly  $D_2(f) = L(f)$  does not imply that  $f \in \mathcal{M}$ . Take for example  $f: [0, 1] \rightarrow R$  given by  $f(x) = 0, x \in [0, 1/4] \cup \{1/2\}, f(x) = x$  otherwise.

*Proof of Theorem 3.*

A(i) This is part (ii) of Lemma 4.

(ii) Let  $u \in L(g) = \bigcup_{n=1}^{\infty} [\xi_n, \eta_n]$  by Lemma 3, then  $u \in [\xi_n, \eta_n]$  some  $n$  and  $g(x) = g(\xi_n)$  for all  $x \in [\xi_n, \eta_n]$ . Since  $g \in \mathcal{M}$ , using the properties of  $L(g)$  we conclude that  $g(x) < g(\xi_n)$  for all  $x \in [a, \xi_n)$ . It follows from the definition of  $g$  that  $g(\xi_n) = f(\xi_n) - \theta/w(\xi_n)$  and

$$f(x) - \theta/w(x) \leq f(\xi_n) - \theta/w(\xi_n) \quad \text{for all } x \in [\xi_n, \eta_n].$$

It follows that  $u \in L(f - \theta/w)$ .

Now if  $u \in D_2(f - \theta/w) = \bigcup_{n=1}^{\infty} [\gamma_n, \delta_n]$  by Lemma 3, then  $u \in [\gamma_n, \delta_n]$  some  $n$ . Also

$$f(x) - \theta/w(x) \leq f(\gamma_n) - \theta/w(\gamma_n) \quad \text{for all } x \in [\gamma_n, \delta_n].$$

Using the definition of  $g$  we conclude that  $g(x) = g(\gamma_n)$  for all  $x \in [\gamma_n, \delta_n]$ . Hence  $u \in L(g)$ . This proves the equality of two sets. The assertion concerning  $P$  follows from the properties of  $P$  established in Section 2 of [11].

(iii) Let  $x \in [a, b] - D_1(f - \theta/w)$ . We assert that if  $a \leq y < x$  then

$$f(y) - \theta/w(y) \leq f(x) - \theta/w(x).$$

If, on the contrary, for some  $y$ ,  $a \leq y < x$ ,

$$f(y) - \theta/w(y) > f(x) - \theta/w(x)$$

holds, then let

$$t = \sup\{u: u \in [y, x], f(u) - \theta/w(u) = \max_{z \in [y, x]} (f(z) - \theta/w(z))\}.$$

Clearly  $a \leq t < x$  and by continuity of  $f - \theta/w$  there exists  $v$ ,  $x < v$  such that

$$f(z) - \theta/w(z) < f(t) - \theta/w(t) \quad \text{for all } z \in (t, v).$$

Hence,  $x \in D_1(f - \theta/w)$ , a contradiction. This establishes the validity of the assertion made above. It follows from the definition of  $g$  that  $g(x) = f(x) - \theta/w(x)$ .

Now suppose  $x \in D_1(f - \theta/w) = \bigcup_{n=1}^{\infty} (\gamma_n, \delta_n)$  by Lemma 3. Then  $x \in (\gamma_n, \delta_n)$  some  $n$ . Hence

$$f(z) - \theta/w(z) < f(\gamma_n) - \theta/w(\gamma_n), \quad \text{for all } z \in (\gamma_n, \delta_n).$$

We then have

$$g(x) \geq g(\gamma_n) \geq f(\gamma_n) - \theta/w(\gamma_n) > f(x) - \theta/w(x).$$

(iv) From Lemma 3 it follows that  $L(g) = \bigcup_{n=1}^{\infty} [\xi_n, \eta_n]$ , where  $[\xi_n, \eta_n]$  are disjoint intervals. Hence  $L^{(0)}(g) = \bigcup_{n=1}^{\infty} (\xi_n, \eta_n)$  is an open set and  $g^{(n)}(x) = 0$  for all  $x \in L^{(0)}(g)$ ,  $n = 1, 2, \dots$ . From part (ii) we have  $L^{(0)}(g) = D_2^{(0)}(f - \theta/w)$ .

(v) Since  $g$  is nondecreasing, it follows that  $g$  is differentiable  $\mu^*$ -a.e. (see [9], p. 96.) By (iv),  $g^{(1)}(x) = 0$  on  $D_2^{(0)}(f - \theta/w)$  and the result follows.

(B) If  $D_2(f) = \emptyset$  then  $D_2^{(0)}(f) = \emptyset$  and the  $\mu^*$ -measures of these two sets are equal to 0. Suppose  $D_2(f) \neq \emptyset$ , then by Lemma 3  $D_2(f) = \bigcup_{n=1}^{\infty} [\lambda_n, \mu_n]$  where the intervals  $[\lambda_n, \mu_n]$  all disjoint. Hence  $D_2^{(0)}(f) = \bigcup_{n=1}^{\infty} (\lambda_n, \mu_n)$ . It follows that the set  $D_2(f) - D_2^{(0)}(f)$  is at most countable and therefore the  $\mu^*$ -measures of these sets are equal.

The proof of the remaining part is similar to the one used in showing that the Cantor ternary function is not absolutely continuous. Let

$$H = [a, b] - D_2^{(0)}(f - \theta/w).$$

Clearly  $H$  is compact and  $a, b \in H$ . By hypothesis  $\mu^*(H) = 0$ . Let  $\epsilon > 0$ . From the theory of Lebesgue measure we conclude that there exists a countable sequence of open intervals  $(x_i, y_i)$ ,  $i = 1, 2, \dots$ ,  $-\infty < x_i < y_i < \infty$  such that  $H \subset \bigcup_{i=1}^{\infty} (x_i, y_i)$  and  $\sum_{i=1}^{\infty} |y_i - x_i| < \epsilon$ . Since  $H$  is compact, by taking finite unions and renumbering if necessary, we can find a finite covering  $(x_i, y_i)$ ,  $i = 1, 2, \dots, n$  of  $H$  such that  $x_i < y_i < x_{i+1} < y_{i+1}$ ,  $i = 1, 2, \dots, n-1$  and  $a \in (x_1, y_1)$ ,  $b \in (x_n, y_n)$ . Now  $D_2^{(0)}(f - \theta/w) \subset L(g)$  by A(ii) and the former set is a countable union of open intervals on each of which  $g$  is constant, it follows that  $g(y_i) = g(x_{i+1})$ ,  $i = 1, 2, \dots, n-1$ . Thus

$$|b - x_n| + \sum_{i=2}^{n-1} |y_i - x_i| + |y_1 - a| < \epsilon$$

and

$$\eta = g(b) - g(a) = g(b) - g(x_n) + \sum_{i=2}^{n-1} (g(y_i) - g(x_i)) + g(y_1) - g(a)$$

Since by hypothesis  $\eta > 0$ , it follows that  $g$  is not absolutely continuous. We showed in Theorem 2 of [11] that if  $f$  and  $w$  are absolutely continuous then so is  $g$ . Hence both  $f$  and  $w$  cannot be absolutely continuous.

The proof of Theorem 3 is now complete.

We remark that part B may also be proved by applying Theorem 13, p. 106 of [9] to  $g$ .

## 5. ALGORITHMS

In this section we consider the problem (1.2) with  $X = [a, b]$  as in Section 4 and develop algorithms to compute  $g$  and  $\bar{g}$  defined by (4.1) and (4.2), respectively. Specifically we let  $G_n$ ,  $n = 1, 2, \dots$  be a sequence of finite sets contained in  $[a, b]$  such that  $G_n$  becomes dense in  $[a, b]$  as  $n \rightarrow \infty$  and construct a sequence of functions  $g_n(\bar{g}_n)$ ,  $n = 1, 2, \dots$  defined on  $[a, b]$  but depending on  $G_n$  such that  $g_n(\bar{g}_n)$  converges uniformly to  $g(\bar{g})$  as  $n \rightarrow \infty$ . We also establish rates of convergence of various quantities involved. We now state the following:

**THEOREM 4.** *Let  $f, w \in \mathcal{C}$ ,  $f \notin \mathcal{M}$ . Let  $G_n \subset [a, b]$ ,  $n = 1, 2, \dots$  be a sequence of finite sets such that  $a, b \in G_n$  for all  $n$  and*

$$\delta_n = \sup_{x \in [a, b]} \inf_{y \in G_n} |x - y| \rightarrow 0 \quad \text{as } n \rightarrow \infty.$$

Let

$$S_n = \{(x, y) \in G_n \times G_n : x, y \in G_n, x \leq y\}$$

and

$$\theta_n = \max_{(x, y) \in S_n} \frac{w(x) w(y)}{w(x) + w(y)} (f(x) - f(y)).$$

Define also

$$M_f = \max_{x \in [a, b]} |f(x)|,$$

$$M_w = \max_{x \in [a, b]} |w(x)|,$$

$$m_w = \min_{x \in [a, b]} |w(x)|.$$

We then have

(A)  $\theta_n \leq \theta$  for all  $n$  and  $\theta_n \rightarrow \theta$  as  $n \rightarrow \infty$  according to

$$0 \leq \theta - \theta_n \leq (M_w^2/m_w) \lambda(f, \delta_n) + (M_w^2 M_f/m_w^2) \lambda(w, \delta_n), \quad (5.1)$$

where

$$\lambda(h, \delta) = \max_{|x-y| \leq \delta, x, y \in [a, b]} |h(x) - h(y)|, \quad h \in \mathcal{C}$$

is the modulus of continuity of  $h$ . (See [8].)

(B) Define  $g_n, \bar{g}_n: [a, b] \rightarrow R$  by

$$g_n(x) = \max_{z \in [a, x] \cap G_n} (f(z) - \theta_n/w(z)), \quad x \in G_n,$$

$$\bar{g}_n(x) = \min_{z \in [x, b] \cap G_n} (f(z) + \theta_n/w(z)), \quad x \in G_n,$$

and for  $x \in [a, b] - G_n$  choose any value of  $g_n(x)$  ( $\bar{g}_n(x)$ ) that will make the function  $g_n$  ( $\bar{g}_n$ ) nondecreasing on  $[a, b]$  (e.g., choose linear interpolation or form a step function). Then  $g_n$  ( $= g_n$  or  $\bar{g}_n$ ) converges to  $g$  ( $= g$  or  $\bar{g}$ , respectively) uniformly according to

$$\begin{aligned} & \sup_{x \in [a, b]} |g(x) - g_n(x)| \\ & \leq M_w^2/m_w^2 + 2) \lambda(f, \delta_n) + (1/m_w^2)(M_w^2 M_f/m_w + 2\theta) \lambda(w, \delta_n). \end{aligned} \quad (5.2)$$

(C) Define  $g_n, \bar{g}_n: [a, b] \rightarrow R$  by

$$g_n(x) = \max_{z \in [a, x] \cap G_n} (f(z) - \theta/w(z)), \quad x \in G_n,$$

$$\bar{g}_n(x) = \min_{z \in [x, b] \cap G_n} (f(z) + \theta/w(z)), \quad x \in G_n,$$

and for  $x \in [a, b] - G_n$  choose any value of  $g_n(x)(\bar{g}_n(x))$  as in (B) that will make the function  $g_n(\bar{g}_n)$  nondecreasing on  $[a, b]$ . Then  $g_n \leq g \leq \bar{g} \leq \bar{g}_n$  and  $g_n(=g_n \text{ or } \bar{g}_n)$  converges to  $g(=g \text{ or } \bar{g}, \text{ respectively})$  uniformly according to

$$\sup_{x \in [a, b]} |g(x) - g_n(x)| \leq 2\lambda(f, \delta_n) + (2\theta/m_w^2) \lambda(w, \delta_n). \quad (5.3)$$

(D) If  $G_n$  in addition satisfies

$$G_n \subset G_{n+1} \quad \text{for all } n,$$

then

$$g_n(x) \leq g_{n+m}(x) \leq \bar{g}_{n+m}(x) \leq \bar{g}_n(x) \quad \text{for all } x \in G_n \\ \text{all } n, m \geq 1,$$

where  $g_n$  and  $\bar{g}_n$  are as defined in (B) or (C).

*Proof of Theorem 4.*

(A) Clearly,  $\theta_n \leq \theta$ . There exist  $x, y \in [a, b]$ ,  $x < y$  and  $f(x) > f(y)$  such that

$$\theta = (w(x)w(y)/(w(x) + w(y)))(f(x) - f(y)).$$

It is easy to see that there exist  $x_n, y_n \in G_n$  such that  $|x - x_n| \leq \delta_n$ ,  $|y - y_n| \leq \delta_n$ ,  $x_n \leq y_n$ . Then

$$\theta_n \geq (w(x_n)w(y_n)/(w(x_n) + w(y_n)))(f(x_n) - f(y_n)).$$

Hence,

$$\theta - \theta_n \leq \frac{w(x)w(y)}{w(x) + w(y)}(f(x) - f(x_n) + f(y_n) - f(y)) \\ + \left( \frac{w(x)w(y)}{w(x) + w(y)} - \frac{w(x_n)w(y_n)}{w(x_n) + w(y_n)} \right) (f(x_n) - f(y_n)). \quad (5.4)$$

Now

$$\frac{w(x)w(y)}{w(x) + w(y)} - \frac{w(x_n)w(y_n)}{w(x_n) + w(y_n)} \\ = \frac{w(x)w(x_n)(w(y) - w(y_n)) + w(y)w(y_n)(w(x) - w(x_n))}{(w(x) + w(y))(w(x_n) + w(y_n))}.$$

Hence

$$\frac{w(x)w(y)}{w(x) + w(y)} - \frac{w(x_n)w(y_n)}{w(x_n) + w(y_n)} \leq \frac{M_w^2}{2m_w^2} \lambda(w, \delta_n).$$

Also  $|f(x_n) - f(y_n)| \leq 2M_f$  and

$$\frac{w(x)w(y)}{w(x) + w(y)}(f(x) - f(x_n) + f(y_n) - f(y)) \leq \frac{M_w^2}{m_w} \lambda(f, \delta_n).$$

Using the above bounds in (5.4) we may deduce (5.1).

(B) We show the result for  $g_n$ , the proof for  $\bar{g}_n$  is similar. Let  $x \in [a, b]$ , then by the definition of  $g$ , there exists  $z \in [a, x]$  such that  $g(x) = f(z) - \theta/w(z)$ . There exists  $u \in G_n$  such that  $0 \leq z - u \leq 2\delta_n$  and hence

$$g_n(x) \geq g_n(u) \geq f(u) - \theta_n/w(u) \geq f(u) - \theta/w(u),$$

the last inequality following from the fact that  $\theta_n \leq \theta$ . We conclude that

$$\begin{aligned} g(x) - g_n(x) &\leq f(z) - f(u) + \theta(w(z) - w(u))/(w(z) w(u)) \\ &\leq \lambda(f, 2\delta_n) + (\theta/m_w^2) \lambda(w, 2\delta_n). \end{aligned}$$

Since  $\lambda(f, k\delta_n) \leq k\lambda(f, \delta_n)$ , where  $k$  is a positive integer, we have,

$$g(x) - g_n(x) \leq 2\lambda(f, \delta_n) + (2\theta/m_w^2) \lambda(w, \delta_n). \quad (5.5)$$

Now if  $x \in [a, b]$ , then there exists  $v \in [a, b]$  such that  $0 \leq v - x \leq 2\delta_n$ . Then by the definition of  $g_n$ , we have

$$g_n(x) \leq g_n(v) = f(t) - \theta_n/w(t) \quad (5.6)$$

for some  $t \in [a, v] \cap G_n$ . If  $t \leq x$ , we have

$$g(x) \geq g(t) \geq f(t) - \theta/w(t)$$

and from (5.6), (5.1) we conclude that

$$g_n(x) - g(x) \leq (\theta - \theta_n)/w(t) \leq (M_w^2/m_w^2) \lambda(f, \delta_n) + (M_w^2 M_f/m_w^3) \lambda(w, \delta_n). \quad (5.7)$$

If, on the other hand,  $x < t \leq v$ , we observe that  $g(x) \geq f(x) - \theta/w(x)$  and from (5.6) obtain,

$$g_n(x) - g(x) \leq f(t) - f(x) + (\theta - \theta_n)/w(t) + \theta(w(t) - w(x))/(w(t) w(x))$$

which by (5.1) reduces to

$$g_n(x) - g(x) \leq (M_w^2/m_w^2 + 2) \lambda(f, \delta_n) + (1/m_w^2)(M_w^2 M_f/m_w + 2\theta) \lambda(w, \delta_n). \quad (5.8)$$

Comparing (5.7) and (5.8) we see that (5.8) holds for all  $x \in [a, b]$ . The required result (5.2) is then derived from (5.5) and (5.8).

(C) This may be proved using arguments similar to those used to prove (B).

(D) This is evident.
